## Outline

- 34 This is the readable version of the TRES tidyverse tutorial. A convenient PDF
- $_{35}$  version can be downloaded by clicking the PDF document icon in the header
- 36 bar.

#### About

- The TRES tidyverse tutorial is an online workshop on how to use the tidyverse,
- <sup>39</sup> a set of packages in the R computing language designed at making data handling
- 40 and plotting easier.
- This tutorial will take the form of a one hour per week video stream via Google
- Meet, every Friday morning at 10.00 (Groningen time) starting from the 29th
- 43 of May, 2020 and lasting for a couple of weeks (depending on the number of
- topics we want to cover, but there should be at least 5).
- 45 PhD students from outside our department are welcome to attend.

#### 46 Schedule

Topic	Package	Instructor	Date*
Reading data and string manipulation	readr, stringr, glue	Pratik	29/05/20
Data and reshaping	tibble, tidyr	Raphael	05/06/20
Manipulating data	dplyr	Theo	12/06/20
Working with lists and iteration	purrr	Pratik	19/06/20
Plotting	ggplot2	Raphael	26/06/20
Regular expressions	regex	Richel	03/07/20
Programming with the tidyverse	rlang	Pratik	10/07/20

6 CONTENTS

## Possible extras

• Reproducibility and package-making (with e.g. usethis)

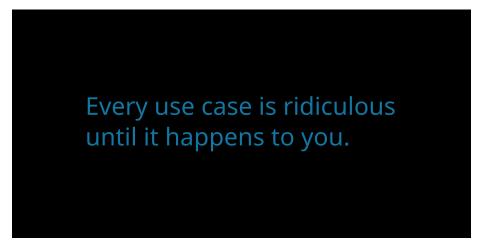

• Embedding C++ code with Rcpp

## Join

- Join the Slack by clicking this link (Slack account required).
- \*Tentative dates.

## 54 Chapter 1

# Reading files and stringmanipulation

58 Load the packages for the day.

library(readr)
library(stringr)
library(glue)

## 1.1 Data import and export with readr

- $_{\rm 60}$  Data in the wild with which ecologists and evolutionary biologists deal is most
- often in the form of a text file, usually with the extensions .csv or .txt. Often,
- such data has to be written to file from within R. readr contains a number of

functions to help with reading and writing text files.

#### 64 1.1.1 Reading data

- Reading in a csv file with readr is done with the read\_csv function, a faster
- alternative to the base R read.csv. Here, read\_csv is applied to the mtcars
- 67 example.

```
# get the filepath of the example
some_example = readr_example("mtcars.csv")
  # read the file in
some_example = read_csv(some_example)
head(some_example)
  #> # A tibble: 6 x 11
                                                                                                                         hp drat
                                 mpq
                                                             cyl disp
                                                                                                                                                                                   wt qsec
                                                                                                                                                                                                                                                                       am gear carb
                                                                                                                                                                                                                                           vs

                                                                                                                                                                                                                                                                            0
                                                                                                                                                                                                                                                                                                        3
                                                                                                                                                                                                                                                                                                                                     2
                                                                                         360
                                                                                                                       105 2.76 3.46 20.2
  #> 6 18.1
                                                                       6
                                                                                         225
                                                                                                                                                                                                                                                1
                                                                                                                                                                                                                                                                                                                                     1
```

- The read\_csv2 function is useful when dealing with files where the separator
- between columns is a semicolon;, and where the decimal point is represented
- 70 by a comma,.

72

- 71 Other variants include:
  - read\_tsv for tab-separated files, and
- read\_delim, a general case which allows the separator to be specified manually.
- readr import function will attempt to guess the column type from the first N
- 76 lines in the data. This N can be set using the function argument guess\_max.
- The n\_max argument sets the number of rows to read, while the skip argument
- 78 sets the number of rows to be skipped before reading data.
- 79 By default, the column names are taken from the first row of the data, but they
- can be manually specified by passing a character vector to col\_names.
- 81 There are some other arguments to the data import functions, but the defaults
- <sup>82</sup> usually just work.

#### 1.1.2 Writing data

- Writing data uses the write\_\* family of functions, with implementations for csv, csv2 etc. (represented by the asterisk), mirroring the import functions discussed above. write\_\* functions offer the append argument, which allow a data frame to be added to an existing file.
- 88 These functions are not covered here.

#### 89 1.1.3 Reading and writing lines

- 90 Sometimes, there is text output generated in R which needs to be written to file,
- but is not in the form of a dataframe. A good example is model outputs. It is
- good practice to save model output as a text file, and add it to version control.
- $_{93}$  Similarly, it may be necessary to import such text, either for display to screen,
- 94 or to extract data.
- 95 This can be done using the readr functions read\_lines and write\_lines. Con-
- 96 sider the model summary from a simple linear model.

```
# get the model
model = lm(mpg ~ wt, data = mtcars)
```

- 97 The model summary can be written to file. When writing lines to file, BE
- $_{98}$  AWARE OF THE DIFFERENCES BETWEEN UNIX AND WINODWS line
- 99 separators. Usually, this causes no trouble.

```
# capture the model summary output
model_output = capture.output(summary(model))
# save it to file
write_lines(x = model_output,
    path = "model_output.txt")
```

This model output can be read back in for display, and each line of the model output is an element in a character vector.

```
# read in the model output and display
model_output = read_lines("model_output.txt")

# use cat to show the model output as it would be on screen
cat(model_output, sep = "\n")

#>
#> Call:
#> lm(formula = mpg ~ wt, data = mtcars)
#>
#> Residuals:
#> Min   1Q Median   3Q   Max
#> -4.543 -2.365 -0.125  1.410  6.873
#>
```

These few functions demonstrate the most common uses of readr, but most other use cases for text data can be handled using different function arguments, including reading data off the web, unzipping compressed files before reading, and specifying the column types to control for type conversion errors.

#### Excel files

112

Finally, data is often shared or stored by well meaning people in the form of Microsoft Excel sheets. Indeed, Excel (especially when synced regularly to remote storage) is a good way of noting down observational data in the field. The readxl package allows importing from Excel files, including reading in specific sheets.

## 1.2 String manipulation with stringr

stringr is the tidyverse package for string manipulation, and exists in an interesting symbiosis with the stringi package. For the most part, stringr is a wrapper around stringi, and is almost always more than sufficient for day-to-day needs.

stringr functions begin with str\_.

#### 1.2.1 Putting strings together

Concatenate two strings with str\_c, and duplicate strings with str\_dup. Flatten a list or vector of strings using str\_flatten.

```
# str_c works like paste(), choose a separator
str_c("this string", "this other string", sep = "_")
#> [1] "this string_this other string"

# str_dup works like rep
str_dup("this string", times = 3)
#> [1] "this stringthis stringthis string"

# str_flatten works on lists and vectors
```

str\_flatten(string = as.list(letters), collapse = "\_")

```
str_flatten(string = letters, collapse = "-")
   \#>[1] "a-b-c-d-e-f-q-h-i-j-k-l-m-n-o-p-q-r-s-t-u-v-w-x-y-z"
  str_flatten is especially useful when displaying the type of an object that
  returns a list when class is called on it.
   # get the class of a tibble and display it as a single string
   class tibble = class(tibble::tibble(a = 1))
   str_flatten(string = class_tibble, collapse = ", ")
   #> [1] "tbl_df, tbl, data.frame"
          Detecting strings
   1.2.2
   Count the frequency of a pattern in a string with str count. Returns an integer.
   Detect whether a pattern exists in a string with str detect. Returns a logical
   and can be used as a predicate.
   Both are vectorised, i.e, automatically applied to a vector of arguments.
   # there should be 5 a-s here
   str_count(string = "ababababa", pattern = "a")
   #> [17 5]
   # vectorise over the input string
   # should return a vector of length 2, with integers 5 and 3
   str_count(string = c("ababbababa", "banana"), pattern = "a")
   #> [1] 5 3
   # vectorise over the pattern to count both a-s and b-s
   str_count(string = "ababababa", pattern = c("a", "b"))
   #> [1] 5 4
128 Vectorising over both string and pattern works as expected.
   # vectorise over both string and pattern
   # counts a-s in first input, and b-s in the second
   str_count(string = c("ababababa", "banana"),
             pattern = c("a", "b"))
   #> \[ \int 1 \] 5 1
   # provide a longer pattern vector to search for both a-s
   # and b-s in both inputs
   str_count(string = c("ababababa", "banana"),
             pattern = c("a", "b",
                         "b", "a"))
   #> [1] 5 1 4 3
```

the elements.

120

str\_locate locates the search pattern in a string, and returns the start and end as a two column matrix.

```
# the behaviour of both str_locate and str_locate_all is
   # to find the first match by default
   str locate(string = "banana", pattern = "ana")
   #>
          start end
   #> [1,]
               2
   # str detect detects a sequence in a string
   str_detect(string = "Bananageddon is coming!",
              pattern = "na")
   #> [1] TRUE
   # str_detect is also vectorised and returns a two-element logical vector
   str_detect(string = "Bananageddon is coming!",
               pattern = c("na", "don"))
   #> [1] TRUE TRUE
   # use any or all to convert a multi-element logical to a single logical
   # here we ask if either of the patterns is detected
   any(str_detect(string = "Bananageddon is coming!",
                   pattern = c("na", "don")))
   #> [1] TRUE
131 Detect whether a string starts or ends with a pattern. Also vectorised. Both
have a negate argument, which returns the negative, i.e., returns FALSE if the
search pattern is detected.
   # taken straight from the examples, because they suffice
   fruit <- c("apple", "banana", "pear", "pineapple")</pre>
   # str_detect looks at the first character
   str_starts(fruit, "p")
   #> [1] FALSE FALSE TRUE TRUE
   # str ends looks at the last character
   str_ends(fruit, "e")
   #> [1] TRUE FALSE FALSE TRUE
   # an example of negate = TRUE
   str_ends(fruit, "e", negate = TRUE)
   #> [1] FALSE TRUE TRUE FALSE
   str_subset [WHICH IS NOT RELATED TO str_sub] helps with subsetting a
   character vector based on a str_detect predicate. In the example, all elements
   containing "banana" are subset.
   str which has the same logic except that it returns the vector position and not
```

#### 1.2.3 Matching strings

str\_match returns all positive matches of the pattern in the string. The return type is a list, with one element per search pattern.

A simple case is shown below where the search pattern is the phrase "banana".

The search pattern can be extended to look for multiple subsets of the search pattern. Consider searching for dates and times.

Here, the search pattern is a regex pattern that looks for a set of four digits (\\d{4}) and a month name (\\w+) seperated by a hyphen. There's much more to be explored in dealing with dates and times in lubridate, another tidyverse package.

The return type is a list, each element is a character matrix where the first column is the string subset matching the full search pattern, and then as many columns as there are parts to the search pattern. The parts of interest in the search pattern are indicated by wrapping them in parentheses. For example, in the case below, wrapping [-.] in parentheses will turn it into a distinct part of the search pattern.

```
pattern = "(\d{4})[-.](\w+)")
                             [,2] [,3]
                             "1970" "somemonth"
#> [1,] "1970-somemonth"
#> [2,] "1990-anothermonth" "1990" "anothermonth"
#> [3,] "2010-thismonth"
                            "2010" "thismonth"
# then with [-.] actively searched for
str_match(string = c("1970-somemonth-01",
                     "1990-anothermonth-01",
                     "2010-thismonth-01"),
          pattern = "(\d{4})([-.])(\w+)")
#>
        [,1]
                             [,2] [,3] [,4]
#> [1,] "1970-somemonth"
                             "1970" "-" "somemonth"
#> [2,] "1990-anothermonth" "1990" "-" "anothermonth"
                            "2010" "-" "thismonth"
#> [3,] "2010-thismonth"
Multiple possible matches are dealt with using str_match_all. An example
case is uncertainty in date-time in raw data, where the date has been entered
as 1970-somemonth-01 or 1970/anothermonth/01.
The return type is a list, with one element per input string. Each element is a
character matrix, where each row is one possible match, and each column after
the first (the full match) corresponds to the parts of the search pattern.
# first with a single date entry
str_match_all(string = c("1970-somemonth-01 or maybe 1990/anothermonth/01"),
              pattern = "(\d{4})[\-\]([a-z]+)")
#> [[1]]
#>
       [,1]
                             [,2] \quad [,3]
                             "1970" "somemonth"
#> [1,] "1970-somemonth"
#> [2,] "1990/anothermonth" "1990" "anothermonth"
# then with multiple date entries
str_match_all(string = c("1970-somemonth-01 or maybe 1990/anothermonth/01",
                          "1990-somemonth-01 or maybe 2001/anothermonth/01"),
              pattern = "(\d{4})[\-\]([a-z]+)")
#> [[1]]
        [,1]
                             [,2]
                                   [,3]
#> [1,] "1970-somemonth"
                            "1970" "somemonth"
#> [2,] "1990/anothermonth" "1990" "anothermonth"
#>
#> [[2]]
       [,1]
                             [,2] [,3]
#>
#> [1,] "1990-somemonth"
                            "1990" "somemonth"
#> [2,] "2001/anothermonth" "2001" "anothermonth"
```

#### 1.2.4 Simpler pattern extraction

```
The full functionality of str_match_* can be boiled down to the most com-
         mon use case, extracting one or more full matches of the search pattern using
163
         str_extract and str_extract_all respectively.
164
         str_extract returns a character vector with the same length as the input string
165
         vector, while str_extract_all returns a list, with a character vector whose
166
         elements are the matches.
         # extracting the first full match using str extract
         str_extract(string = c("1970-somemonth-01 or maybe 1990/anothermonth/01",
                                                                     "1990-somemonth-01 or maybe 2001/anothermonth/01"),
                                        pattern = "(\d{4})[\-\]([a-z]+)")
         #> [1] "1970-somemonth" "1990-somemonth"
         # extracting all full matches using str_extract all
         str_extract_all(string = c("1970-somemonth-01 or maybe 1990/anothermonth/01",
                                                                                "1990-somemonth-01 or maybe 2001/anothermonth/01"),
                                                   pattern = "(\d{4})[\-\]([a-z]+)")
         #> \(\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma\Gamma
         #> [1] "1970-somemonth"
                                                                                "1990/anothermonth"
         #> [[2]]
         #> [1] "1990-somemonth"
                                                                                "2001/anothermonth"
         1.2.5
                            Breaking strings apart
         str_split, str_sub, In the above date-time example, when reading filenames
         from a path, or when working sequences separated by a known pattern generally,
170
         str_split can help separate elements of interest.
171
        The return type is a list similar to str_match.
         # split on either a hyphen or a forward slash
         str_split(string = c("1970-somemonth-01",
                                                                "1990/anothermonth/01"),
                                   pattern = "[\\-\\/]")
         #> [[1]]
         #> [1] "1970"
                                                           "somemonth" "01"
         #>
         #> [[2]]
         #> \[ \begin{aligned} \text{17} & \begin{aligned} \text{1990} \\ \text{9} \end{aligned} \]
                                                                   "anothermonth" "01"
```

This can be useful in recovering simulation parameters from a filename, but may require some knowledge of regex.

```
# assume a simulation output file
filename = "sim_param1_0.01_param2_0.05_param3_0.01.ext"
```

```
# not quite there
str_split(filename, pattern = "_")
#> [[1]]
                   "param1" "0.01"
#> [1] "sim"
                                         "param2" "0.05"
                                                                  "param3"
                                                                              "0.01.ext"
# not really
str_split(filename,
           pattern = "sim_")
#> [[17]
#> [17 ""
#> [2] "param1_0.01_param2_0.05_param3_0.01.ext"
# getting there but still needs work
str_split(filename,
           pattern = "(sim_)|_*param\\d{1}_|(.ext)")
#> [[1]]
                      "0.01" "0.05" "0.01" ""
#> [1] ""
str_split_fixed split the string into as many pieces as specified, and can be
especially useful dealing with filepaths.
# split on either a hyphen or a forward slash
str_split_fixed(string = "dir_level_1/dir_level_2/file.ext",
                 pattern = "/",
                 n = 2)
         [.1]
                       [,2]
#> [1,] "dir_level_1" "dir_level_2/file.ext"
1.2.6 Replacing string elements
str_replace is intended to replace the search pattern, and can be co-opted
into the task of recovering simulation parameters or other data from regularly
named files. str_replace_all works the same way but replaces all matches of
the search pattern.
# replace all unwanted characters from this hypothetical filename with spaces
filename = "sim_param1_0.01_param2_0.05_param3_0.01.ext"
str_replace_all(filename,
                 pattern = "(sim_)|_*param\\d{1}_|(.ext)",
                 replacement = " ")
#> [1] " 0.01 0.05 0.01 "
str_remove is a wrapper around str_replace where the replacement is set to
"". This is not covered here.
Having replaced unwanted characters in the filename with spaces, str trim
offers a way to remove leading and trailing whitespaces.
```

```
# trim whitespaces from this filename after replacing unwanted text
   filename = "sim_param1_0.01_param2_0.05_param3_0.01.ext"
   filename_with_spaces = str_replace_all(filename,
                                            pattern = "(sim_)|_*param\\d{1}_|(.ext)",
                                            replacement = " ")
   filename_without_spaces = str_trim(filename_with_spaces)
   filename_without_spaces
   #> [1] "0.01 0.05 0.01"
   # the result can be split on whitespaces to return useful data
   str split(filename without spaces, " ")
   #> [[17]
   #> [1] "0.01" "0.05" "0.01"
   1.2.7
           Subsetting within strings
  When strings are highly regular, useful data can be extracted from a string using
  str_sub. In the date-time example, the year is always represented by the first
189 four characters.
   # get the year as characters 1 - 4
   str_sub(string = c("1970-somemonth-01",
                       "1990-anothermonth-01",
                       "2010-thismonth-01"),
            start = 1, end = 4)
   #> [1] "1970" "1990" "2010"
Similarly, it's possible to extract the last few characters using negative indices.
   # get the day as characters -2 to -1
   str_sub(string = c("1970-somemonth-01",
                       "1990-anothermonth-21",
                       "2010-thismonth-31"),
           start = -2, end = -1)
   Finally, it's also possible to replace characters within a string based on the
   position. This requires using the assignment operator <-.
   # replace all days in these dates to 01
   date times = c("1970-somemonth-25",
                   "1990-anothermonth-21",
                   "2010-thismonth-31")
   # a strictly necessary use of the assignment operator
   str sub(date times,
           start = -2, end = -1) <- "01"
```

```
date_times
#> [1] "1970-somemonth-01" "1990-anothermonth-01" "2010-thismonth-01"
```

#### 1.2.8 Padding and truncating strings

Strings included in filenames or plots are often of unequal lengths, especially when they represent numbers. str\_pad can pad strings with suitable characters to maintain equal length filenames, with which it is easier to work.

97 Strings can also be truncated if they are too long.

#### 1.2.9 Stringr aspects not covered here

199 Some stringr functions are not covered here. These include:

```
• str_wrap (of dubious use),
```

- str\_interp, str\_glue\* (better to use glue; see below),
- str sort, str order (used in sorting a character vector),
- str\_to\_case\* (case conversion), and
- str\_view\* (a graphical view of search pattern matches).
- word, boundary etc. The use of word is covered below.
- stringi, of which stringr is a wrapper, offers a lot more flexibility and control.

## 1.3 String interpolation with glue

- The idea behind string interpolation is to procedurally generate new complex strings from pre-existing data.
- glue is as simple as the example shown.

215

216

github page.

```
# print that each car name is a car model
cars = rownames(head(mtcars))
glue('The {cars} is a car model')
#> The Mazda RX4 is a car model
#> The Mazda RX4 Wag is a car model
#> The Datsun 710 is a car model
#> The Hornet 4 Drive is a car model
#> The Hornet Sportabout is a car model
#> The Valiant is a car model
This creates and prints a vector of car names stating each is a car model.
The related glue_data is even more useful in printing from a dataframe. In
this example, it can quickly generate command line arguments or filenames.
# use dataframes for now
parameter_combinations = data.frame(param1 = letters[1:5],
                                      param2 = 1:5)
# for command line arguments or to start multiple job scripts on the cluster
glue_data(parameter_combinations,
           'simulation-name {param1} {param2}')
#> simulation-name a 1
#> simulation-name b 2
#> simulation-name c 3
#> simulation-name d 4
#> simulation-name e 5
# for filenames
glue_data(parameter_combinations,
           'sim data param1 {param1} param2 {param2}.ext')
#> sim_data_param1_a_param2_1.ext
#> sim_data_param1_b_param2_2.ext
#> sim_data_param1_c_param2_3.ext
#> sim data param1 d param2 4.ext
#> sim_data_param1_e_param2_5.ext
Finally, the convenient glue_sql and glue_data_sql are used to safely write
SQL queries where variables from data are appropriately quoted. This is not
covered here, but it is good to know it exists.
glue has some more functions — glue_safe, glue_collapse, and glue_col,
but these are infrequently used. Their functionality can be found on the glue
```

#### $_{\scriptscriptstyle 20}$ 1.4 ${ m Strings}$ in <code>ggplot</code>

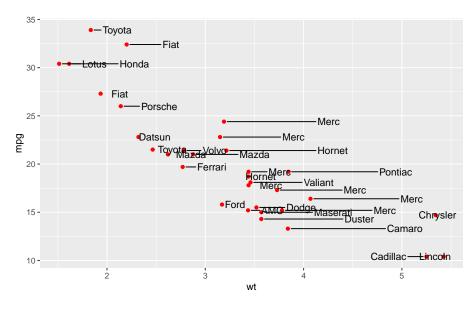

ggplot has two geoms (wait for the ggplot tutorial to understand more about geoms) that work with text: geom\_text and geom\_label. These geoms allow text to be pasted on to the main body of a plot.

Often, these may overlap when the data are closely spaced. The package ggrepel offers another geom, geom\_text\_repel (and the related
geom\_label\_repel) that help arrange text on a plot so it doesn't overlap with other features. This is not perfect, but it works more often than
not.

229 More examples can be found on the ggrepl website.

Here, the arguments to geom\_text\_repel are taken both from the mtcars data (position), as well as from the car brands extracted using the stringr::word (labels), which tries to separate strings based on a regular pattern.

The details of ggplot are covered in a later tutorial.

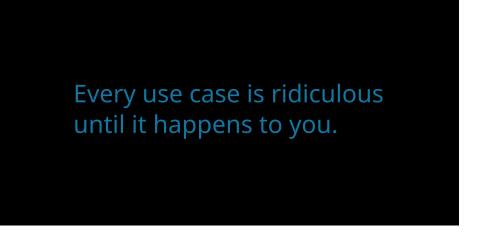

This is not a good looking plot, because it breaks other rules of plot design, such as whether this sort of plot should be made at all. Labels and text need to be applied sparingly, for example drawing attention or adding information to outliers.

## Chapter 2

Reshaping data tables in the tidyverse, and other things

244 Raphael Scherrer

245

library(tibble)
library(tidyr)

In this chapter we will learn what tidy means in the context of the tidyverse, and how to reshape our data into a tidy format using the tidyr package. But

first, let us take a detour and introduce the tibble.

#### $_{19}$ 2.1 The new data frame: tibble

The tibble is the recommended class to use to store tabular data in the tidyverse. Consider it as the operational unit of any data science pipeline. For most practical purposes, a tibble is basically a data.frame.

```
# Make a data frame
data.frame(who = c("Pratik", "Theo", "Raph"), chapt = c("1, 4", "3", "2, 5"))
       who chapt
#> 1 Pratik 1, 4
      Theo
#> 2
#> 3
      Raph 2, 5
# Or an equivalent tibble
tibble(who = c("Pratik", "Theo", "Raph"), chapt = c("1, 4", "3", "2, 5"))
#> # A tibble: 3 x 2
    who
          chapt
     <chr> <chr>
#> 1 Pratik 1, 4
#> 2 Theo 3
#> 3 Raph
           2, 5
```

The difference between tibble and data.frame is in its display and in the way it is subsetted, among others. Most functions working with data.frame will work with tibble and vice versa. Use the as\* family of functions to switch back and forth between the two if needed, using e.g. as.data.frame or as\_tibble.

In terms of display, the tibble has the advantage of showing the class of each column: chr for character, fct for factor, int for integer, dbl for numeric and lgl for logical, just to name the main atomic classes. This may be more important than you think, because many hard-to-find bugs in R are due to wrong variable types and/or cryptic type conversions. This especially happens with factor and character, which can cause quite some confusion. More about this in the extra section at the end of this chapter!

Note that you can build a tibble by rows rather than by columns with tribble:

```
tribble(
    ~who, ~chapt,
    "Pratik", "1, 4",
    "Theo", "3",
    "Raph", "2, 5"
)

#> # A tibble: 3 x 2
#> who chapt
#> <chr> <chr> #> 1 Pratik 1, 4
#> 2 Theo 3
```

```
#> 3 Raph
                2, 5
   As a rule of thumb, try to convert your tables to tibbles whenever you can,
   especially when the original table is not a data frame. For example, the prin-
266
   cipal component analysis function prcomp outputs a matrix of coordinates in
   principal component-space.
   # Perform a PCA on mtcars
   pca_scores <- prcomp(mtcars)$x</pre>
   head(pca_scores) # looks like a data frame or a tibble...
                              PC1
                                    PC2
                                          PC3
                                                  PC4
                                                         PC5
                                                                 PC6
                                                                           PC7
                                                                                   PC8

                                                                        0.356 -0.0906
                                                     -0.0243
                                                               0.221
                 30.8
                        3.34 -0.521
                                                               -0.0530
   #> 5 129.
                                      0.737 -0.333
                                                      0.106
                                                                        0.153 - 0.189
```

This is important because a matrix can contain only one type of values (e.g. only numeric or character), while tibble (and data.frame) allow you to have columns of different types.

#> # ... with 26 more rows, and 1 more variable: PC11 <dbl>

0.803 -0.0884

0.239

0.424

0.101 -0.0377

#> 6 -23.2 35.1 -3.26 1.40

272 So, in the tidyverse we are going to work with tibbles, got it. But what does 273 "tidy" mean exactly?

#### 2.2 The concept of tidy data

When it comes to putting data into tables, there are many ways one could organize a dataset. The *tidy* format is one such format. According to the formal definition, a table is tidy if each column is a variable and each row is an observation. In practice, however, I found that this is not a very operational definition, especially in ecology and evolution where we often record multiple variables per individual. So, let's dig in with an example.

Say we have a dataset of several morphometrics measured on Darwin's finches in the Galapagos islands. Let's first get this dataset.

```
# We first simulate random data
beak_lengths <- rnorm(100, mean = 5, sd = 0.1)
beak_widths <- rnorm(100, mean = 2, sd = 0.1)
body weights <- rgamma(100, shape = 10, rate = 1)
islands <- rep(c("Isabela", "Santa Cruz"), each = 50)
# Assemble into a tibble
data <- tibble(</pre>
  id = 1:100,
 body_weight = body_weights,
 beak_length = beak_lengths,
 beak_width = beak_widths,
  island = islands
# Snapshot
data
#> # A tibble: 100 x 5
        id body_weight beak_length beak_width island
#>
     \langle int \rangle
              <\!db\,l> <\!db\,l> <\!db\,l> <\!chr>
#> 1
                10.8
                              4.94
                                         1.94 Isabela
       1
#> 2
        2
                             5.02
               15.4
                                         2.00 Isabela
        3
               15.0
                             4.92
                                        1.91 Isabela
#> 4
        4
                 8.51
                             5.16
                                         2.02 Isabela
#> 5
        5
                 14.9
                              5.03
                                         1.93 Isabela
#> 6
       6
                8.41
                              4.92
                                         2.18 Isabela
#> # ... with 94 more rows
```

Here, we pretend to have measured beak\_length, beak\_width and body\_weight on 100 birds, 50 of them from Isabela and 50 of them from Santa Cruz. In this tibble, each row is an individual bird. This is probably the way most scientists would record their data in the field. However, a single bird is not an "observation" in the sense used in the tidyverse. Our dataset is not tidy but messy.

The tidy equivalent of this dataset would be:

289

290

291

292

294

295

296

297

299

301

302

303

304

306

#> island

#>

Isabela

Santa Cruz

```
data <- pivot_longer(</pre>
  data,
  cols = c("body_weight", "beak_length", "beak_width"),
  names_to = "variable"
)
data
#> # A tibble: 300 x 4
         id island variable
                                   va.l.u.e
      \langle int \rangle \langle chr \rangle
                                   <dbl>
          1 Isabela body weight 10.8
          1 Isabela beak length 4.94
          1 Isabela beak width
                                    1.94
          2 Isabela body_weight 15.4
          2 Isabela beak_length 5.02
          2 Isabela beak_width
#> # ... with 294 more rows
where each measurement (and not each individual) is now the unit of observation
(the rows). The pivot_longer function is the easiest way to get to this format.
It belongs to the tidyr package, which we'll cover in a minute.
As you can see our tibble now has three times as many rows and fewer columns.
This format is rather unintuitive and not optimal for display. However, it pro-
vides a very standardized and consistent way of organizing data that will be
understood (and expected) by pretty much all functions in the tidyverse. This
makes the tidyverse tools work well together and reduces the time you would
otherwise spend reformatting your data from one tool to the next.
That does not mean that the messy format is useless though. There may be
use-cases where you need to switch back and forth between formats. For this
reason I prefer referring to these formats using their other names: long (tidy)
versus wide (messy). For example, matrix operations work much faster on wide
data, and the wide format arguably looks nicer for display. Luckily the tidyr
package gives us the tools to reshape our data as needed, as we shall see shortly.
Another common example of wide-or-long dilemma is when dealing with con-
tingency tables. This would be our case, for example, if we asked how many
observations we have for each morphometric and each island. We use table
(from base R) to get the answer:
# Make a contingency table
ctg <- with(data, table(island, variable))</pre>
ctg
#>
                 variable
```

A variety of statistical tests can be used on contingency tables such as Fisher's

50

50

beak\_length beak\_width body\_weight

50

50

50

exact test, the chi-square test or the binomial test. Contingency tables are in
the wide format by construction, but they too can be pivoted to the long format,
and the tidyverse manipulation tools will expect you to do so. Actually, tibble
knows that very well and does it by default if you convert your table into a
tibble:

```
# Contingency table is pivoted to the long-format automatically
as_tibble(ctg)
#> # A tibble: 6 x 3
     island
                variable
                                 n.
     <chr>
                <chr>
                             <int>
#> 1 Isabela
                beak_length
                                50
#> 2 Santa Cruz beak length
                                50
#> 3 Isabela
                beak\_width
                                50
#> 4 Santa Cruz beak width
                                50
#> 5 Isabela
                body weight
                                50
#> 6 Santa Cruz body weight
                                50
```

#### 2.3 Reshaping with tidyr

The tidyr package implements tools to easily switch between layouts and also perform a few other reshaping operations. Old school R users will be familiar with the reshape and reshape2 packages, of which tidyr is the tidyverse equivalent. Beware that tidyr is about playing with the general layout of the dataset, while operations and transformations of the data are within the scope of the dplyr and purrr packages. All these packages work hand-in-hand really well, and analysis pipelines usually involve all of them. But today, we focus on the first member of this holy trinity, which is often the first one you'll need because you will want to reshape your data before doing other things. So, please hold your non-layout-related questions for the next chapters.

#### 2.3.1 Pivoting

Pivoting a dataset between the long and wide layout is the main purpose of tidyr (check out the package's logo). We already saw the pivot\_longer function above. This function converts a table form wide to long format. Similarly, there is a pivot\_wider function that does exactly the opposite and takes you back to the wide format:

```
pivot_wider(
  data,
  names_from = "variable",
  values_from = "value",
  id_cols = c("id", "island")
)
#> # A tibble: 100 x 5
```

```
#>
       id island body_weight beak_length beak_width
#>
    <int> <chr>
                       <dbl>
                                   <dbl>
#> 1
                       10.8
                                    4.94
      1 Isabela
                                              1.94
                       15.4
                                    5.02
        2 Isabela
                                              2.00
       3 Isabela
                                               1.91
#> 3
                       15.0
                                    4.92
        4 Isabela
                        8.51
                                    5.16
                                               2.02
#> 5
        5 Isabela
                        14.9
                                    5.03
                                               1.93
        6 Isabela
                        8.41
                                    4.92
                                               2.18
#> # ... with 94 more rows
```

The order of the columns is not exactly as it was, but this should not matter in a data analysis pipeline where you should access columns by their names. It is straightforward to change the order of the columns, but this is more within the scope of the dplyr package.

If you are familiar with earlier versions of the tidyverse, pivot\_longer and pivot\_wider are the respective equivalents of gather and spread, which are now deprecated.

There are a few other reshaping operations from tidyr that are worth knowing.

#### <sup>339</sup> 2.3.2 Handling missing values

Say we have some missing measurements in the column "value" of our finch dataset:

```
# We replace 100 random observations by NAs
ii <- sample(nrow(data), 100)</pre>
data$value[ii] <- NA
data
#> # A tibble: 300 x 4
        id island variable
                                  va.l.v.e.
     \langle int \rangle \langle chr \rangle \langle chr \rangle
                                  <dbl>
#> 1
        1 Isabela body_weight 10.8
#> 2
         1 Isabela beak length NA
#> 3
        1 Isabela beak width NA
#> 4
         2 Isabela body_weight NA
         2 Isabela beak length 5.02
         2 Isabela beak_width NA
#> # ... with 294 more rows
```

We could get rid of the rows that have missing values using drop\_na:

Else, we could replace the NAs with some user-defined value:

```
replace na(data, replace = list(value = -999))
#> # A tibble: 300 x 4
#>
        id island variable
                                   value
#>
    \langle int \rangle \langle chr \rangle \langle chr \rangle
                                    <dbl>
                                   10.8
         1 Isabela body_weight
#> 2
         1 Isabela beak_length -999
        1 Isabela beak width -999
#> 4
        2 Isabela body_weight -999
         2 Isabela beak_length
#> 6
        2 Isabela beak_width -999
#> # ... with 294 more rows
```

where the replace argument takes a named list, and the names should refer to the columns to apply the replacement to.

We could also replace NAs with the most recent non-NA values:

#### fill(data, value)

```
#> # A tibble: 300 x 4
       id island variable
                             value
    <int> <chr> <chr>
                             <dbl>
       1 Isabela body_weight 10.8
#> 1
#> 2
        1 Isabela beak length 10.8
        1 Isabela beak width 10.8
      2 Isabela body_weight 10.8
       2 Isabela beak length 5.02
#> 6
        2 Isabela beak width
                              5.02
#> # ... with 294 more rows
```

Note that most functions in the tidyverse take a tibble as their first argument, and columns to which to apply the functions are usually passed as "objects" rather than character strings. In the above example, we passed the value column as value, not "value". These column-objects are called by the tidyverse functions in the context of the data (the tibble) they belong to.

#### <sup>2</sup> 2.3.3 Splitting and combining cells

- The tidyr package offers tools to split and combine columns. This is a nice extension to the string manipulations we saw last week in the stringr tutorial.
- Say we want to add the specific dates when we took measurements on our birds

(we would normally do this using dplyr but for now we will stick to the old way):

```
# Sample random dates for each observation
data$day <- sample(30, nrow(data), replace = TRUE)</pre>
data$month <- sample(12, nrow(data), replace = TRUE)</pre>
data$year <- sample(2019:2020, nrow(data), replace = TRUE)</pre>
data
#> # A tibble: 300 x 7
     id island variable value day month year
\#> <int><chr>< <chr>< <dbl><int><int><int><
#> 1
      1 Isabela body_weight 10.8 8 7 2020
       1 Isabela beak_length NA
                                   19
                                         7 2019
#> 3
      1 Isabela beak_width NA
                                  17 12 2019
      2 Isabela body_weight NA 20 12 2020
#> 4
      2 Isabela beak_length 5.02 21 10 2020
#> 5
#> 6 2 Isabela beak_width NA 23 2 2020
#> # ... with 294 more rows
```

We could combine the day, month and year columns into a single date column, with a dash as a separator, using unite:

```
data <- unite(data, day, month, year, col = "date", sep = "-")</pre>
data
#> # A tibble: 300 x 5
     id island variable
                          value date
   \langle int \rangle \langle chr \rangle \langle chr \rangle \langle dbl \rangle \langle chr \rangle
1 Isabela beak_length NA 19-7-2019
#> 2
2 Isabela body_weight NA
#> 4
                                20-12-2020
#> 5 2 Isabela beak_length 5.02 21-10-2020
#> 6 2 Isabela beak width NA 23-2-2020
#> # ... with 294 more rows
```

Of course, we can revert back to the previous dataset by splitting the date column with separate.

```
#> # ... with 294 more rows
```

- But note that the day, month and year columns are now of class character and not integer anymore. This is because they result from the splitting of date, which itself was a character column.
- You can also separate a single column into multiple rows using separate\_rows:

```
separate_rows(data, date)
#> # A tibble: 900 x 5
        id island variable value date
    \langle int \rangle \langle chr \rangle \langle chr \rangle \langle dbl \rangle \langle chr \rangle
#> 1
        1 Isabela body_weight 10.8 8
#> 2
          1 Isabela body_weight 10.8 7
#> 3
        1 Isabela body_weight 10.8 2020
#> 4
        1 Isabela beak_length NA 19
#> 5
        1 Isabela beak_length NA
                                         7
#> 6
         1 Isabela beak length NA
                                         2019
#> # ... with 894 more rows
```

#### 2.3.4 Expanding tables using combinations

Instead of getting rid of rows with NAs, we may want to add rows with NAs, for example, for combinations of parameters that we did not measure.

```
data <- separate(data, date, into = c("day", "month", "year"))</pre>
to_rm <- with(data, island == "Santa Cruz" & year == "2020")
data <- data[!to_rm,]</pre>
tail(data)
#> # A tibble: 6 x 7
      id island variable value day month year
   #> 1 98 Santa Cruz beak_length 4.94 22 12
                                          2019
#> 2
      98 Santa Cruz beak_width 1.90 9
                                      1
                                            2019
#> 3
      99 Santa Cruz body_weight 15.0 16
                                       7
                                            2019
#> 4 99 Santa Cruz beak length NA
                               26
                                      10
                                          2019
#> 5
    99 Santa Cruz beak width 2.04 30
                                     7
                                            2019
    100 Santa Cruz beak width NA
                                  23
                                       3
                                            2019
```

We could generate a tibble with all combinations of island, morphometric and year using expand\_grid:

```
expand_grid(
   island = c("Isabela", "Santa Cruz"),
   year = c("2019", "2020")
)
#> # A tibble: 4 x 2
#> island year
#> <chr> <chr>
```

375

378

380

```
#> 1 Isabela
                 2019
#> 2 Isabela
                 2020
#> 3 Santa Cruz 2019
#> 4 Santa Cruz 2020
If we already have a tibble to work from that contains the variables to combine,
we can use expand on that tibble:
expand(data, island, year)
#> # A tibble: 4 x 2
#>
     island
                year
    \langle chr \rangle
                 <chr>
#> 1 Isabela
                 2019
#> 2 Isabela
                 2020
#> 3 Santa Cruz 2019
#> 4 Santa Cruz 2020
As you can see, we get all the combinations of the variables of interest, even
those that are missing. But sometimes you might be interested in variables
that are nested within each other and not crossed. For example, say we have
measured birds at different locations within each island:
nrow_Isabela <- with(data, length(which(island == "Isabela")))</pre>
nrow_SantaCruz <- with(data, length(which(island == "Santa Cruz")))</pre>
sites_Isabela <- sample(c("A", "B"), size = nrow_Isabela, replace = TRUE)
sites_SantaCruz <- sample(c("C", "D"), size = nrow_SantaCruz, replace = TRUE)</pre>
sites <- c(sites_Isabela, sites_SantaCruz)</pre>
data$site <- sites
data
#> # A tibble: 232 x 8
                                value day
        id island variable
                                             month year site
     <int> <chr> <chr>
                                <dbl> <chr> <chr> <chr> <chr> <chr> <chr>
        1 Isabela body_weight 10.8 8
                                               7
#> 1
                                                     2020 A
                                               7
         1 Isabela beak_length NA
                                        19
                                                     2019
         1 Isabela beak_width NA
                                        17
                                               12
                                                     2019 B
         2 Isabela body_weight NA
                                        20
                                               12
                                                     2020 A
         2 Isabela beak_length 5.02 21
#> 5
                                               10
                                                     2020 A
          2 Isabela beak_width NA
                                        23
                                                     2020
#> # ... with 226 more rows
Of course, if sites A and B are on Isabela, they cannot be on Santa Cruz, where
we have sites C and D instead. It would not make sense to expand assuming
that island and site are crossed, instead, they are nested. We can therefore
expand using the nesting function:
expand(data, nesting(island, site, year))
#> # A tibble: 6 x 3
    island site year
     \langle ch.r \rangle
                <chr> <chr>
```

```
#> 1 Isabela
                 A
                       2019
#> 2 Isabela
                 A
                       2020
#> 3 Isabela
                 В
                       2019
#> 4 Isabela
                B
                       2020
#> 5 Santa Cruz C
                       2019
#> 6 Santa Cruz D
                       2019
```

- But now the missing data for Santa Cruz in 2020 are not accounted for because
- expand thinks the year is also nested within island. To get back the missing
- combination, we use crossing, the complement of nesting:

```
expand(data, crossing(nesting(island, site), year)) # both can be used together
```

```
#> # A tibble: 8 x 3
     island
                 site year
                 <chr> <chr>
#>
     <chr>
#> 1 Isabela
                 \boldsymbol{A}
                        2019
#> 2 Isabela
                        2020
                 A
#> 3 Isabela
                 B
                       2019
#> 4 Isabela
                 B
                        2020
#> 5 Santa Cruz C
                        2019
#> 6 Santa Cruz C
                        2020
#> # ... with 2 more rows
```

- Here, we specify that site is nested within island and these two are crossed with site. Easy!
- But wait a minute. These combinations are all very good, but our measurements have disappeared! We can get them back by levelling up to the complete
- function instead of using expand:

#### tail(complete(data, crossing(nesting(island, site), year)))

```
#> # A tibble: 6 x 8
#>
     island
               site year
                               id variable
                                              value day
                                                          month
     <chr>
                <chr> <chr> <int> <chr>
                                              <dbl> <chr> <chr>
#> 1 Santa Cruz D
                            95 beak_width NA
                      2019
                                                    13
                                                          10
#> 2 Santa Cruz D
                      2019
                               98 beak_length 4.94 22
#> 3 Santa Cruz D
                      2019
                               99 body_weight 15.0 16
                                                          7
#> 4 Santa Cruz D
                               99 beak_length NA
                                                    26
                                                          10
                      2019
#> 5 Santa Cruz D
                                                          7
                      2019
                               99 beak_width
                                               2.04 30
#> 6 Santa Cruz D
                      2020
                               NA <NA>
                                              NA
                                                    <NA>
                                                          <NA>
# the last row has been added, full of NAs
```

which nicely keeps the rest of the columns in the tibble and just adds the missing combinations.

#### $_{\scriptscriptstyle 91}$ 2.3.5 Nesting

- $_{392}$  The tidyr package has yet another feature that makes the tidyverse very pow-
- erful: the nest function. However, it makes little sense without combining it

with the functions in the purrr package, so we will not cover it in this chapter but rather in the purrr chapter.

#### $_{\circ}$ 2.4 Extra: factors and the forcats package

```
library(forcats)
```

Categorical variables can be stored in R as character strings in character or factor objects. A factor looks like a character, but it actually is an integer vector, where each integer is mapped to a character label. With this respect it is sort of an enhanced version of character. For example,

```
my_char_vec <- c("Pratik", "Theo", "Raph")
my_char_vec
#> [1] "Pratik" "Theo" "Raph"
```

is a character vector, recognizable to its double quotes, while

```
my_fact_vec <- factor(my_char_vec) # as.factor would work too
my_fact_vec
#> [1] Pratik Theo Raph
#> Levels: Pratik Raph Theo
```

is a factor, of which the *labels* are displayed. The *levels* of the factor are the unique values that appear in the vector. If I added an extra occurrence of my name:

```
factor(c(my_char_vec, "Raph"))
#> [1] Pratik Theo Raph Raph
#> Levels: Pratik Raph Theo
```

we would still have the the same levels. Note that the levels are returned as a character vector in alphabetical order by the levels function:

```
levels(my_fact_vec)
#> [1] "Pratik" "Raph" "Theo"
```

Why does it matter? Well, most operations on categorical variables can be performed on character of factor objects, so it does not matter so much which one you use for your own data. However, some functions in R require you to provide categorical variables in one specific format, and others may even implicitly convert your variables. In ggplot2 for example, character vectors are converted into factors by default. So, it is always good to remember the differences and what type your variables are.

But this is a tidyverse tutorial, so I would like to introduce here the package forcats, which offers tools to manipulate factors. First of all, most tools from stringr will work on factors. The forcats functions expand the string manipulation toolbox with factor-specific utilities. Similar in philosophy to stringr where functions started with str\_, in forcats most functions start with fct\_.

#### 36CHAPTER 2. RESHAPING DATA TABLES IN THE TIDYVERSE, AND OTHER THINGS

- I see two main ways forcats can come handy in the kind of data most people
- deal with: playing with the order of the levels of a factor and playing with the
- levels themselves. We will show here a few examples, but the full breadth of
- factor manipulations can be found online or in the excellent forcats cheatsheet.

#### 2.4.1 Change the order of the levels

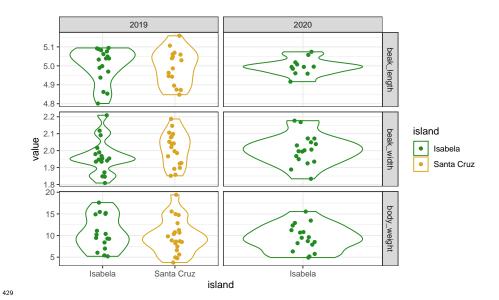

```
One example use-case where you would want to change the order of the levels
of a factor is when plotting. Your categorical variable, for example, may not be
plotted in the order you want. If we plot the distribution of each variable across
```

islands, we get

```
# Make the plotting code a function so we can re-use it without copying and pasting
my_plot <- function(data) {

# We do not cover the ggplot functions in this chapter, this is just to
# illustrate our use-case, wait until chapter 5!
library(ggplot2)
ggplot(data, aes(x = island, y = value, color = island)) +
    geom_violin() +
    geom_jitter(width = 0.1) +
    facet_grid(variable ~ year, scales = "free") +
    theme_bw() +
    scale_color_manual(values = c("forestgreen", "goldenrod"))
}

my_plot(data)
# Remember that data are missing from Santa Cruz in 2020</pre>
```

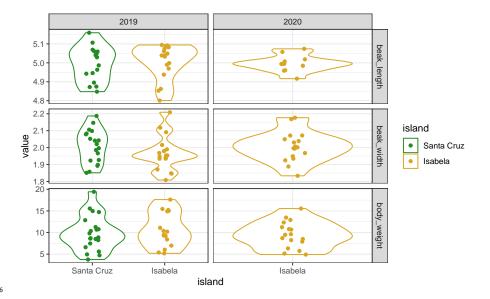

Here, the islands (horizontal axis) and the variables (the facets) are displayed in alphabetical order. When making a figure you may want to customize these orders in such a way that your message is optimally conveyed by your figure,

434 Use fct\_relevel to manually change the order of the levels:

and this may involve playing with the order of levels.

data\$island <- as.factor(data\$island) # turn this column into a factor
data\$island <- fct\_relevel(data\$island, c("Santa Cruz", "Isabela"))
my\_plot(data) # order of islands has changed!</pre>

433

Beware that reordering a factor *does not change* the order of the items within
the vector, only the order of the *levels*. So, it does not introduce any mistmatch
between the **island** column and the other columns! It only matters when the
levels are called, for example, in a ggplot. As you can see:

```
data$island[1:10]
#> [1] Isabela Isabela Isabela Isabela Isabela Isabela Isabela Isabela Isabela
#> [10] Isabela
#> Levels: Santa Cruz Isabela
```

fct\_relevel(data\$island, c("Isabela", "Santa Cruz"))[1:10] # same thing, different lev
#> [1] Isabela Isabela Isabela Isabela Isabela Isabela Isabela Isabela
#> [10] Isabela
#> Levels: Isabela Santa Cruz

Alternatively, use fct\_inorder to set the order of the levels to the order in which they appear:

```
data$variable <- as.factor(data$variable)
levels(data$variable)
#> [1] "beak_length" "beak_width" "body_weight"
levels(fct_inorder(data$variable))
#> [1] "body_weight" "beak_length" "beak_width"
```

or fct\_rev to reverse the order of the levels:

```
levels(fct_rev(data$island)) # back in the alphabetical order
#> [1] "Isabela" "Santa Cruz"
```

Other variants exist to do more complex reordering, all present in the forcats cheatsheet, for example: \* fct\_infreq to re-order according to the frequency

of each level (how many observation on each island?) \* fct\_shift to shift
the order of all levels by a certain rank (in a circular way so that the last one
becomes the first one or vice versa) \* fct\_shuffle if you want your levels in
random order \* fct\_reorder, which reorders based on an associated variable
(see fct\_reorder2 for even more complex relationship between the factor and
the associated variable)

#### $_{452}$ 2.4.2 Change the levels themselves

Changing the levels of a factor will change the labels in the actual vector. It is similar to performing a string substitution in stringr. One can change the levels of a factor using fct recode:

or collapse factor levels together using fct\_collapse:

```
fct_collapse(my_fact_vec, EU = c("Theo", "Raph"), NonEU = "Pratik")
#> [1] NonEU EU EU
#> Levels: NonEU EU
```

Again, we do not provide an exhaustive list of forcats functions here but the most usual ones, to give a glimpse of many things that one can do with factors. So, if you are dealing with factors, remember that forcats may have handy tools for you. Among others: \*fct\_anon to "anonymize", i.e. replace the levels by random integers \*fct\_lump to collapse levels together based on their frequency (e.g. the two most frequent levels together)

#### <sup>463</sup> 2.4.3 Dropping levels

If you use factors in your tibble and get rid of one level, for any reason, the factor will usually remember the old levels, which may cause some problems when applying functions to your data.

```
data <- data[data$island == "Santa Cruz",] # keep only one island
unique(data$island) # Isabela is gone from the labels
#> [1] Santa Cruz
#> Levels: Santa Cruz Isabela
levels(data$island) # but not from the levels
#> [1] "Santa Cruz" "Isabela"
```

Use droplevels (from base R) to make sure you get rid of levels that are not in your data anymore:

```
data <- droplevels(data)
levels(data$island)
#> [1] "Santa Cruz"
```

- 469 Fortunately, most functions within the tidyverse will not complain about missing
- levels, and will automatically get rid of those inexistant levels for you. But
- because factors are such common causes of bugs, keep this in mind!
- Note that this is equivalent to doing:

data\$island <- fct\_drop(data\$island)</pre>

#### $^{173}$ 2.4.4 Other things

Among other things you can use in forcats: \* fct\_count to get the frequency
of each level \* fct\_c to combine factors together

#### <sup>176</sup> 2.4.5 Take home message for forcats

Use this package to manipulate your factors. Do you need factors? Or are character vectors enough? That is your call, and may depend on the kind of analyses you want to do and what they require. We saw here that for plotting, having factors can allow you to do quite some tweaking of the display. If you encounter a situation where the order of encoding of your character vector starts to matter, then maybe converting into a factor would make your life easier. And if you do so, remember that lots of tools to perform all kinds of manipulation are available to you with both stringrand forcats.

## Chapter 3

# Data manipulation with dplyr

```
# load the tidyverse
library(tidyverse)
```

#### 493 3.1 Introduction

- Reminders from last weeks: pipe operator, tidy tables, ggplot
- Why dplyr? dplyr vs base R

### 496 3.2 Example data of the day

- 497 Through this tutorial, we will be using mammal trait data from the Phylacine
- database. The dataset contains information on mass, diet, life habit, etc, for
- more than all living species of mammals. Let's have a look.

# phylacine <- readr::read\_csv("data/phylacine\_traits.csv") phylacine</pre>

```
#> #
       Aerial <dbl>, Life. Habit. Method <chr>, Life. Habit. Source <chr>,
       Mass.q <dbl>, Mass.Method <chr>, Mass.Source <chr>, Mass.Comparison <chr>,
       Mass.Comparison.Source <chr>, Island.Endemicity <chr>,
#> #
       IUCN. Status. 1.2 <chr>, Added. IUCN. Status. 1.2 <chr>, Diet. Plant <dbl>,
#> #
       Diet. Vertebrate <dbl>, Diet. Invertebrate <dbl>, Diet. Method <chr>,
#> #
       Diet.Source <chr>
Note the friendly output given by the tibble (as opposed to a data.frame).
readr automatically stores the content it reads in a tibble, tidyverse oblige.
You should know however that dplyr doesn't require your data to be in a tibble,
a regular data.frame will work just as fine.
Most of the dplyr verbs covered in the next sections assume your data is tidy:
wide format, variables as column, 1 observation per row. Not that tehy won't
work if your data isn't tidy, but the results could be very different from what
I'm going to show here. Fortunately, the phylacine trait dataset appears to be
tidy: there is one unique entry for each species.
The first operation I'm going to run on this table is changing the names with
rename(). Some people prefer their tea without sugar, and I prefer my variable
names without uppercase characters, dots or (if possible) numbers. This will
give me the opportunity to introduce the trivial syntax of dplyr verbs.
phylacine <- phylacine %>%
  dplyr::rename(
    "binomial" = Binomial.1.2,
    "order" = Order.1.2,
    "family" = Family.1.2,
    "genus" = Genus.1.2,
    "species" = Species.1.2,
    "terrestrial" = Terrestrial,
    "marine" = Marine,
    "freshwater" = Freshwater,
    "aerial" = Aerial,
    "life_habit_method" = Life.Habit.Method,
    "life habit source" = Life.Habit.Source,
    "mass_g" = Mass.g,
    "mass_method" = Mass.Method,
    "mass_source" = Mass.Source,
    "mass_comparison" = Mass.Comparison,
    "mass comparison source" = Mass.Comparison.Source,
    "island endemicity" = Island. Endemicity,
    "iucn_status" = IUCN.Status.1.2, # not even for acronyms
    "added_iucn_status" = Added.IUCN.Status.1.2,
    "diet_plant" = Diet.Plant,
    "diet vertebrate" = Diet.Vertebrate,
    "diet invertebrate" = Diet.Invertebrate,
```

"diet\_method" = Diet.Method,

```
"diet_source" = Diet.Source
      )
   For convenience, I'm going to use the pipe operator (%>%) that we've seen before,
   through this chapter. All dplyr functions are built to work with the pipe (i.e,
   their firstargument is always data), but again, this is not compulsory. I could
   phylacine <- dplyr::rename(</pre>
      data = phylacine,
      "binomial" = Binomial.1.2,
   )
   Note how columns are referred to. Once the data as been passed as an argument,
   no need to refer to it anymore, dplyr understands that you're dealing with
   variables inside that data frame. So drop that data$var, data[, "var"], and,
   if you've read The R book, forget the very existence of attach().
520
   Finally, I should mention that you can refer to variables names either with
521
   strings or directly as objects, whether you're reading or creating them:
   phylacine2 <- readr::read_csv("data/phylacine_traits.csv")</pre>
   phylacine2 %>%
      dplyr::rename(
        # this works
        binomial = Binomial.1.2
      )
   phylacine2 %>%
      dplyr::rename(
        # this works too!
        binomial = "Binomial.1.2"

# Working with lists and iteration

# load the tidyverse
library(tidyverse)

### 4.1 List columns with tidyr

#### 4.1.1 Nesting data

It may become necessary to indicate the groups of a tibble in a somewhat more explicit way than simply using dplyr::group\_by. tidyr offers the option to create nested tibbles, that is, to store complex objects in the columns of a tibble.

This includes other tibbles, as well as model objects and plots.

- NB: Nesting data is done using tidyr::nest, which is different from the similarly named tidyr::nesting.
- The example below shows how mtcars can be converted into a nested tibble.

```
# nest mtcars into a list of dataframes based on number of cylinders
nested_cars = as_tibble(mtcars,
                        rownames = "car_name") %>%
  group_by(cyl) %>%
  nest()
nested_cars
#> # A tibble: 3 x 2
               cyl [3]
#> # Groups:
       cyl data
     <dbl> <list>
#>
#> 1
         6 <tibble [7 x 11]>
         4 <tibble [11 x 11]>
#> 2
         8 <tibble [14 x 11]>
#> 3
# get column class
sapply(nested_cars, class)
#>
         cyl
                  data
#> "numeric"
                "list"
```

- mtcars is now a nested data frame. The class of each of its columns is respectively, a numeric (number of cylinders) and a list (the data of all cars with as many cylinders as in the corresponding row).
- While nest can be used without first grouping the tibble, it's just much easier to group first.

#### $_{52}$ 4.1.2 Unnesting data

A nested tibble can be converted back into the original, or into a processed form, using tidyr::unnest. The original groups are retained.

```
# use unnest to recover the original data frame
unnest(nested_cars, cols = "data")
 #> # A tibble: 32 x 12
 #> # Groups:
                                                                        cyl [3]
                                                                                                                            mpg disp
                                                                                                                                                                                                                                                      wt qsec
 #>

 # unnesting preserves groups
groups(unnest(nested_cars, cols = "data"))
 #> [[1]]
 #> cyl
The unnest_longer and unnest_wider variants of unnest are maturing func-
tions, that is, not in their final form. They allow interesting variations on
unnesting — these are shown here but advised against.
Unnest the data first, and then convert it to the form needed.

                                                                       cyl [3]
                                                                                                                                                                                                                                                                 qsec vs
                                                                                                                                                                                                                                                                                                                                                       gear carb
                                  cyl car_name mpg
                                                                                                                                     disp
                                                                                                                                                                      hp
                                                                                                                                                                                                        drat wt
                                                                                                                                                                                                                                                                                                                         am
                         <dbl> <list>
                                                                                                   6 < chr [7] > < dbl ~ < dbl 
 #> 1
                                           8 < chr [14^{\sim} < dbl \sim < db
                                   Working with list columns
4.1.3
The class of a list column is list, and working with list columns (and lists, and
list-like objects such as vectors) makes iteration necessary, since this is one of
the only ways to operate on lists.
Two examples are shown below when getting the class and number of rows of
the nested tibbles in the list column.
# how many rows in each nested tibble?
for (i in seq_along(nested_cars$data)) {
```

```
print(nrow(nested_cars$data[[i]]))
#> [1] 7
#> [1] 11
#> [1] 14
# what is the class of each element?
lapply(X = nested_cars$data, FUN = class)
#> [[1]]
#> [1] "tbl df"
                     "tbl"
                                  "data.frame"
#>
#> [[2]]
#> [1] "tbl_df"
                     "tbl"
                                  "data.frame"
#> [[3]]
                                  "data.frame"
#> [1] "tbl_df"
                     "tbl"
```

#### 55 Functionals

The second example uses lapply, and this is a functional. Functionals are functions that take another function as one of their arguments. Base R functionals include the \*apply family of functions: apply, lapply, vapply and so on.

## 569 4.2 Iteration with map

The tidyverse replaces traditional loop-based iteration with functionals from the purr package. A good reason to use purr functionals instead of base R functionals is their consistent and clear naming, which always indicates how they should be used. This is explained in the examples below.

How map is different from for and lapply are best explained in the Advanced R Book.

#### 576 4.2.1 Basic use of map

map works very similarly to lapply, where .x is object on whose elements to apply the function .f.

```
# get the number of rows in data
map(.x = nested_cars$data, .f = nrow)
#> [[1]]
#> [1] 7
#>
#> [[2]]
#> [1] 11
```

```
#> [[3]]
#> [1] 14
map works on any list-like object, which includes vectors, and always returns a
list. map takes two arguments, the object on which to operate, and the function
to apply to each element.
# get the square root of each integer 1 - 10
some_numbers = 1:3
map(some numbers, sqrt)
#> [[1]]
#> [1] 1
#>
#> [[2]]
#> [1] 1.41
#> [[3]]
#> [1] 1.73
        map variants returning vectors
Though map always returns a list, it has variants named map_* where the suffix
indicates the return type. map_chr, map_dbl, map_int, and map_lgl return
character, double (numeric), integer, and logical vectors.
# use map_dbl to get a vector of square roots
some_numbers = 1:10
map_dbl(some_numbers, sqrt)
   [1] 1.00 1.41 1.73 2.00 2.24 2.45 2.65 2.83 3.00 3.16
# map_chr will convert the output to a character
map_chr(some_numbers, sqrt)
#> [1] "1.000000" "1.414214" "1.732051" "2.000000" "2.236068" "2.449490"
   [7] "2.645751" "2.828427" "3.000000" "3.162278"
# map_lgl returns TRUE/FALSE values
some_numbers = c(NA, 1:3, NA, NaN, Inf, -Inf)
map_lgl(some_numbers, is.na)
#> [1] TRUE FALSE FALSE FALSE TRUE TRUE FALSE FALSE
4.2.3
        map variants returning data frames
map_df returns data frames, and by default binds dataframes by rows, while
map_dfr does this explicitly, and map_dfc does returns a dataframe bound by
column.
# split mtcars into 3 dataframes, one per cylinder number
```

some\_list = split(mtcars, mtcars\$cyl)

#> Mazda RX4

*#> Duster 360* 

#> Mazda RX4 Waq

```
# get the first two rows of each dataframe
map_df(some_list, head, n = 2)
                     mpg cyl disp hp drat wt gsec vs am gear carb
                          4 108 93 3.85 2.32 18.6 1 1
                    22.8
#> Datsun 710
#> Merc 240D
                    24.4
                           4 147 62 3.69 3.19 20.0 1 0
                                                                  2
#> Mazda RX4
                    21.0 6 160 110 3.90 2.62 16.5 0 1
#> Mazda RX4 Wag
                    21.0 6 160 110 3.90 2.88 17.0 0 1
#> Hornet Sportabout 18.7 8 360 175 3.15 3.44 17.0 0 0
                                                                  2
#> Duster 360
                    14.3 8 360 245 3.21 3.57 15.8 0 0
map accepts arguments to the function being mapped, such as in the example
above, where head() accepts the argument n = 2.
map_dfr behaves the same as map_df.
# the same as above but with a pipe
some_list %>%
 map dfr(head, n = 2)
                     mpg cyl disp hp drat wt qsec vs am gear carb
#> Datsun 710
                    22.8 4 108 93 3.85 2.32 18.6 1 1
                           4 147 62 3.69 3.19 20.0 1 0
#> Merc 240D
                    24.4
```

map\_dfc binds the resulting 3 data frames of two rows each by column, and automatically repairs the column names, adding a suffix to each duplicate.

#### $_{\scriptscriptstyle{5}}$ 4.2.4 Working with list columns using map

```
The various map versions integrate well with list columns to make synthetic/summary data. In the example, the dplyr::mutate function is used to add three columns to the nested tibble: the number of rows, the mean mileage, and the name of the first car.
```

600 In each of these cases, the vectors added are generated using purrr functions.

```
# get the number of rows per dataframe, the mean mileage, and the first car
nested_cars = nested_cars %>%
  mutate(
    # use the int return to get the number of rows
    n_rows = map_int(data, nrow),
    # double return for mean mileage
    mean_mpg = map_dbl(data, function(df) {mean(df$mpg)}),
    # character return to get first car
    first_car = map_chr(data, function(df) {first(df$car_name)}
    )
  )
# examine the output
nested cars
#> # A tibble: 3 x 5
#> # Groups: cyl [3]
       cyl data
                               n_rows mean_mpg first_car
     <dbl> <list>
                               \langle int \rangle \langle dbl \rangle \langle chr \rangle
        6 <tibble [7 x 11]>
                                  7
#> 1
                                          19.7 Mazda RX4
         4 <tibble [11 x 11]>
                                  11
#> 2
                                           26.7 Datsun 710
         8 <tibble [14 x 11]>
                                   14
                                           15.1 Hornet Sportabout
```

#### of 4.2.5 Selective mapping using map variants

where the data to be added is a mixed list.

```
map_at and map_if work like other *_at and *_if functions. Here, map_if is
used to run a linear model only on those tibbles which have sufficient data. The
predicate is specified by .p.

In this example, the nested tibble is given a new column using dplyr::mutate,
```

The first element is a tibble of the corresponding element in mtcars\$cars, which has not been operated on because it has fewer than 10 rows. The remaining elements are 1m objects.

#### • 4.3 More map variants

map also has variants along the axis of how many elements are operated upon.
map2 operates on two vectors or list-like elements, and returns a single list as
output, while pmap operates on a list of list-like elements. The output has as
many elements as the input lists, which must be of the same length.

#### 4.3.1 Mapping over two inputs with map2

map2 has the same variants as map, allowing for different return types. Here map2\_int returns an integer vector.

map2 doesn't have \_at and \_if variants.

One use case for map2 is to deal with both a list element and its index, as shown in the example. This may be necessary when the list index is removed in a split or nest. This can also be done with imap, where the index is referred to as .y.

# a not particularly useful example

```
map2(this_list, names(this_list),
     function(x, y) {
       glue::glue('{x} : {y}')
#> $a
#> first letter : a
#> $b
#> second letter : b
# imap can also do this
imap(this_list,
     function(x, .y){
       glue::glue('{x} : {.y}')
     })
#> $a
#> first letter : a
#>
#> second letter : b
```

#### 4.3.2 Mapping over multiple inputs with pmap

pmap instead operates on a list of multiple list-like objects, and also comes with
 the same return type variants as map. The example shows both aspects of pmap
 using pmap\_chr.

```
# operate on three different lists
list_01 = as.list(1:3)
list_02 = as.list(letters[1:3])
list_03 = as.list(rainbow(3))

# print a few statements
pmap_chr(list(list_01, list_02, list_03),
    function(11, 12, 13){
        glue::glue('number {11}, letter {12}, colour {13}')}
})

#> [1] "number 1, letter a, colour #FF0000FF"
#> [2] "number 2, letter b, colour #00FF00FF"
#> [3] "number 3, letter c, colour #0000FFFF"
```

#### 4.3.3 Mapping at depth

- Lists are often nested, that is, a list element may itself be a list. It is possible to map a function over elements as a specific depth.
- 630 In the example, mtcars is split by cylinders, and then by gears, creating a

two-level list, with the second layer operated on.

```
# use map to make a 2 level list
this_list = split(mtcars, mtcars$cyl) %>%
    map(function(df){ split(df, df$gear) })

# map over the second level to count the number of
# cars with N gears in the set of cars with M cylinders
# display only for cyl = 4
map_depth(this_list[1], 2, nrow)
#> $`4`
#> $`4`$`3`
#> [1] 1
#>
#> $`4`$`4`
#> [1] 8
#>
#> $`4`$`5`
#> [1] 2
```

#### 32 4.3.4 Iteration without a return

map and its variants have a return type, which is either a list or a vector. However, it is often necessary to iterate a function over a list-like object for that function's side effects, such as printing a message to screen, plotting a series of figures, or saving to file.

walk is the function for this task. It has only the variants walk2, iwalk, and pwalk, whose logic is similar to map2, imap, and pmap. In the example, the function applied to each list element is intended to print a message.

```
this_list = split(mtcars, mtcars$cyl)

iwalk(this_list,
    function(df, .y){
    message(glue::glue('{nrow(df)} cars with {.y} cylinders'))
    })
```

#### 4.3.5 Modify rather than map

When the return type is expected to be the same as the input type, that is, a list returning a list, or a character vector returning the same, modify can help with keeping strictly to those expectations.

In the example, simply adding 2 to each vector element produces an error, because the output is a numeric, or double. modify helps ensure some type safety in this way.

```
vec = as.integer(1:10)
   tryCatch(
     expr = {
        # this is what we want you to look at
       modify(vec, function(x) { (x + 2) })
       },
      # do not pay attention to this
      error = function(e){
       print(toString(e))
     }
   )
   #> [1] "Error: Can't coerce element 1 from a double to a integer\n"
   Converting the output to an integer, which was the original input type, serves
   as a solution.
   modify(vec, function(x) { as.integer(x + 2) })
   #> [1] 3 4 5 6 7 8 9 10 11 12
   A note on invoke
   invoke used to be a wrapper around do.call, and can still be found with its
   family of functions in purrr. It is however retired in favour of functionality
   already present in map and rlang::exec, the latter of which will be covered in
   another session.
653
           Other functions for working with lists
   purr has a number of functions to work with lists, especially lists that are not
   nested list-columns in a tibble.
   4.4.1
           Filtering lists
```

Lists can be filtered on any predicate using keep, while the special case compact is applied when the empty elements of a list are to be filtered out. discard is the opposite of keep, and keeps only elements not satisfying a condition. Again, the predicate is specified by .p.

```
# a list containing numbers
this_list = list(a = 1, b = -1, c = 2, d = NULL, e = NA)
# remove the empty element
```

```
# this must be done before using keep on the list
this_list = compact(this_list)

# use discard to remove the NA
this_list = discard(this_list, .p =is.na)

# keep list elements which are positive
keep(this_list, .p = function(x){ x > 0 })

#> $a
#> [1] 1
#>
#> $c
#> [1] 2
```

head\_while is bit of an odd case, which returns all elements of a list-like object in sequence until the first one fails to satisfy a predicate, specified by .p.

```
1:10 %>%
head_while(.p = function(x) x < 5)
#> [1] 1 2 3 4
```

#### $_{664}$ 4.4.2 Summarising lists

The purr functions every, some, has\_element, detect, detect\_index, and vec\_depth help determine whether a list passes a certain logical test or not.

These are seldom used and are not discussed here.

#### 4.4.3 Reduction and accumulation

reduce helps combine elements along a list using a specific function. Consider the example below where list elements are concatenated into a single vector.

```
this_list = list(a = 1:3, b = 3:4, c = 5:10)
reduce(this_list, c)
#> [1] 1 2 3 3 4 5 6 7 8 9 10
```

This can also be applied to data frames. Consider some random samples of mtcars, each with only 5 cars removed. The objective is to find the cars present in all 10 samples.

The way reduce works in the example below is to take the first element and find its intersection with the second, and to take the result and find its intersection

with the third and so on.

```
# sample mtcars
mtcars = as_tibble(mtcars, rownames = "car")
sampled data = map(1:10, function(x){sample n(mtcars, nrow(mtcars)-5)})
```

```
# get cars which appear in all samples
   sampled_data = reduce(sampled_data, dplyr::inner_join)
   accumulate works very similarly, except it retains the intermediate products.
   The first element is retained as is. accumulate2 and reduce2 work on two lists,
678
   following the same logic as map2 etc. Both functions can be used in much more
   complex ways than demonstrated here.
680
   # make a list
   this_list = list(a = 1:3, b = 3:6, c = 5:10, d = c(1,2,5,10,12))
   # a multiple accumulate can help
   accumulate(this_list, union, .dir = "forward")
   #> $a
   #> [1] 1 2 3
   #>
   #> $b
   #> [1] 1 2 3 4 5 6
   #>
   #> $c
   #> [1] 1 2 3 4 5 6 7 8 9 10
   #> $d
   #> [1] 1 2 3 4 5 6 7 8 9 10 12
```

#### 4.4.4 Miscellaneous operation

purry offers a few more functions to work with lists (or list like objects).

prepend works very similarly to append, except it adds to the head of a list.

splice adds multiple objects together in a list. splice will break the existing list structure of input lists.

```
# use prepend to add values to the head of a list
prepend(x = list("a", "b"), values = list("1", "2"))
#> [[1]]
#> [1] "1"
#>
#> [[2]]
#> [1] "2"
#>
#> [[3]]
#> [1] "a"
#>
#> [[4]]
#> [1] "b"
```

# use splice to add multiple elements together

```
splice(list("a", "b"), list("1", "2"), "something else")
          #> [[1]]
          #> [1] "a"
          #>
          #> [[2]]
          #> [1] "b"
          #>
          #> [[3]]
          #> [1] "1"
          #>
          #> [[4]]
          #> [1] "2"
          #>
          #> [[5]]
          #> [1] "something else"
         flatten has a similar behaviour, and converts a list of vectors or list of lists to a
         single list-like object. flatten_* options allow the output type to be specified.
          this_list = list(a = rep("a", 3),
                                                             b = rep("b", 4))
         this_list
          #> $a
          #> [1] "a" "a" "a"
          #> $b
          #> \[ \begin{aligned} \begin{a
          # use flatten chr to get a character vector
          flatten_chr(this_list)
          #> [1] "a" "a" "a" "b" "b" "b" "b"
         transpose shifts the index order in multi-level lists. This is seen in the example,
         where the gear goes from being the index of the second level to the index of the
         first.
690
          this_list = split(mtcars, mtcars$cyl) %>%
               map(function(df) split(df, df$gear))
          # from a list of lists where cars are divided by cylinders and then
          # gears, this is now a list of lists where cars are divided by
          # gears and then cylinders
          transpose(this_list[1])
          #> $~3~
          #> $`3`$`4`
          #> # A tibble: 1 x 12
          #> car
                                                                                    cyl disp hp drat wt qsec vs
                                                                     mpg
                                                                                                                                                                                                                         am gear carb
```

```
